Data Analysis with Python

Cheat Sheet: Data Wrangling

```
Package/Method Description
                                                                                                    Code Example
                   Replace the
                   missing
                   values of the
                                    1. 1
2. 2
                   data set
Replace missing
                   attribute with
                                     1. MostFrequentEntry = df['attribute name'].value counts().idxmax()
data with
                   the mode
                                     2. df['attribute_name'].replace(np.nan,MostFrequentEntry,`odf['attribute_name'].replace(np.nan,MostFrequentEntry, inplace
frequency
                   common
                                   Copied!
                   occurring
                   entry in the
                   column.
                   Replace the
                   missing
                   values of the
                   data set
Replace missing
                                    1. AverageValue=df['attribute_name'].astype(<data_type>).mean(axis=0)
                   attribute with
data with mean
                                     2. df['attribute_name'].replace(np.nan, AverageValue, inplace=True)
                   the mean of
                   all the
                                  Copied!
                   entries in the
                   column.
                                    1. 1
2. 2
                   Fix the data
                   types of the
                                    1. df[['attribute1_name', 'attribute2_name', ...]] =
2. df[['attribute1_name', 'attribute2_name', ...]].astype('data_type')
3. #data_type is int, float, char, etc.
Fix the data types columns in
                   the
                   dataframe.
                                  Copied!
                   Normalize
                   the data in a
                                    1. 1
                   column such
                                     1. df['attribute_name'] =
Data
                   that the
                                        df['attribute_name']/df['attribute_name'].max()
Normalization
                   values are
                   restricted
                                  Copied!
                   between 0
                   and 1.
                                    2. 2
3. 3
                                     4. 4
                   Create bins
                   of data for

    bins = np.linspace(min(df['attribute name']),

Binning
                   better
                                     2. max(df['attribute_name'],n)
                   analysis and
                                    3. # n is the number of bins needed

4. GroupNames = ['Group1','Group2','Group3,...]

5. df['binned_attribute_name'] =
                   visualization.
                                     6. pd.cut(df['attribute_name'], bins, labels=GroupNames, include_lowest=True)
                                  Copied!
                   Change the
                                     1. 1
                   label name
Change column
                                    1. df.rename(columns={'old_name':\'new_name'}, inplace=True)
                   of a
name
